

CREATING A COURT EXHIBIT¹

A subpoena for a fingerprint case used to mean spending the better part of a day or even longer working in the darkroom and then in front of a drafting table preparing a court display to help the jury better understand how the identification was made.

The first step was to photograph both the latent print and the inked print using 4 x 5 film. Then the film had to be processed and the negatives masked so both prints would be the same size. Once the negatives had been masked, there was yet another trip into the darkroom to print the negatives. The prints were then mounted onto mat board in preparation for the addition of lines and text. If you made a mistake at any point, it generally meant that the damaged print had to be redone — a lot of work just to illustrate how you determined that this particular individual left this faint pattern on an object at the crime scene.

The chart is only part of the process, but it is also one of the more effective techniques used to explain the identification process to a group of individuals that have probably never even noticed that they have their own individual characteristics.

Adobe® Photoshop® makes the task of creating a court display almost pleasurable. It also makes it possible to produce a chart in less than an hour, and after some practice, you'll be able to "knock one out" in about 20 minutes. The techniques used to produce a digital chart are very similar to the taught at schools and seminars around the country by the FBI Latent Section — using film negatives.

Rather than film, we use a charged couple device (CCD) to capture our images. The Kodak digital camera is an example of one kind of capture device that contains a CCD. Instead of using a grid printed on acetate and masking material such as stripper's tape to mask and size our images on a negative, we use the Sizing function and Crop tool in Photoshop to size and crop our images precisely — on screen.

Photoshop's Line and Text tools replace the rub-on lettering and an ink pen for marking minutia. The finished chart is printed onto $8\frac{1}{2}$ " x 11" paper using a high quality dye sublimation printer. Clear acetate can be used in place of the paper if you want to project the chart onto a screen, using an overhead projector. A laser printer can be used to produce draft copies for the Prosecutor or case file. This added flexibility further enhances productivity gains.

The following process will enable you to prepare a court exhibit where numbers or letters are no longer used to identify ridge characteristics. Furthermore, this process focuses not only on ridge characteristics, but on all three levels of fingerprint detail. And it clearly illustrates how a fingerprint identification is made.

A new approach for court exhibits relies not only on "points", but illustrates all three levels of ridge detail.

The first task is to acquire both the latent print and the inked print. When you acquire images either from a digital camera or from a film scanner, the images are not calibrated for one-to-one (1:1), life-size output. In contrast, if you are scanning images using a flatbed scanner, there is no depth of field involved and you specify both the size of the area to be scanned and the image resolution, so images acquired using this particular digital device are acquired as true, life-size images. **NOTE:** It may be that you are scanning a photograph of an image that was enlarged, such as a latent fingerprint that was photographed and then printed as an 8 by 10 inch photograph. In this case, the image may or may not be enlarged by a specific scale, such as a 5 time enlargement, and so forth. Upon scanning this photograph, it would be necessary to rescale the image to print a life-size image. It is also necessary to have a scale (ruler) in an image to be calibrated.

In addition, please be advised that either when scanning an image or photographing an image with a digital camera, it is extremely important to acquire the image at the highest possible resolution in order to ensure the best possible image quality when printing the final court exhibit.

But returning to our original scenario, let's say you are using a digital camera to acquire your latent print and/or your inked print. By way of example, let's say that our CCD chip has a resolution of 2008 pixels by 1504 pixels. You can photograph a one-inch by one-inch area or you can photograph a three-by-five-inch area; it makes absolutely no difference to the camera. But the camera, not being the brightest crayon in the box, has no idea how large the area is that it just captured. All it knows is that the area captured consists of 2008 pixels by 1504 pixels.

Using Adobe[®] Photoshop[®], you can accurately calibrate any image as long as the image has a scale in it. As an alternative to this method, you can also use an image calibration utility, such as the *Foray[®] Technologies* Image Calibration Utility. Both techniques use the same theory — counting the number of pixels from one known point on the scale to another known point on the scale, thus determining the number of pixels per inch for resolution.

NOTE: There are three elements that make up image size of any digital image. First there are the "measurable" physical attributes: width and height. Then there is a more obscure dimension known as resolution (AKA pixels per inch). By knowing one of the measurable attributes, you can determine the other two attributes of image size.

Getting Started

1. Start up Adobe Photoshop, then open the corresponding latent print and known print images, then calibrate both of the images.

NOTE: Record the resolution of both images during the calibration process.

2. Using the calibrated resolution of both images, choose a common denominator.

NOTE: Round the resolution for both images to the nearest 100, and then choose a value that is compatible for both images. For example, if the resolution of the latent print is 1732 PPI and the resolution of the known print is 1689 PPI, the common denominator would be 1700 PPI. If there is a huge disparity in resolution, choose a resolution that is between the two. For example, if the calibrated resolution of the latent print image is 2417 PPI and the calibrated resolution of the known print image is 1200 PPI, use 1800 as the common denominator.)

3. Starting with the latent print (click on the latent print window to make it the active window), from the *Image* menu choose *Image Size*. When the *Image Size* dialog box appears, ensure that *Resample* is enabled (a check mark must appear in the option box to the left of Resample). Highlight the contents of the Resolution field and type the resolution common denominator.

Image Size	×
Pixel Dimensions: 4.42M (was 4.41M)	ОК
Width: 1013 pixels	Cancel
Height: 1525 pixels	Auto
Document Size:	
Width: 0.591 inches	
Height: 0.89 inches	
Resolution: 1713.653 pixels/inch 💌	
Scale Styles	
Constrain Proportions	
Resample Image: Bicubic	

- 4. Click on the known print window to make it the active image. From the *Image* menu choose *Image Size*. When the *Image Size* dialog box appears, ensure that Resample is enabled (a check mark must appear in the option box to the left of Resample). Highlight the contents of the Resolution field and type the resolution common denominator.
- 5. From the *Windows* menu, choose *Arrange* and then choose *Tile Vertically* to display the two images side by side.

Overlaying and aligning the images

1. Starting with the known print (click on the known print window to make it the active window), type the letter **Z** to activate the **Zoom** tool. Position the cursor to the upper left corner of the core on the known print, then click and hold the mouse button and move the cursor to the lower right corner area on the known print.

The center of the image (the core of the known print) will appear in the center of the known print window.

2. Click on the latent print window to make it the active window, then position the *Zoom* cursor (the Zoom cursor is still active from the previous step) to the upper left corner of the core on the latent print, then click and hold the mouse button and move the cursor to the lower right corner area on the latent print.

The center of the image (core of the latent print) will appear in the center of the latent print window.

- 3. Type the letter V to activate the *Move* tool, and then position the point of the *Move* cursor (the tip of the arrowhead) at a unique point within a characteristic that is easily identifiable in both prints.
- 4. Then click and hold the left mouse button and drag the cursor from the latent print window into the known print window, and position the tip of the *Move* cursor (the point of the arrowhead) at the precise, corresponding point of the characteristic identified in the previous step.
- 5. After the latent print has been placed on top of the known print successfully, close the latent print window.

NOTE: Please be careful when closing the latent print window to ensure that you are closing the proper window.

- 6. On the Layers palette of the Known Print window, change the name of the background layer to Known Print by double clicking on the Background layer in the Layers palette. A New Layer dialog box will appear on the screen. In the name text box, type *Known Print* and then click OK.
- Position the cursor directly on top of the words *Layer 1* on the Layers palette and double click the left mouse button. The words *Layer 1* will be highlighted. Type *Latent Print* and then move the cursor to blue area of that layer and click the left mouse button.

Layers Channels F	Paths

er Ø. 🖸 Ø.	

8. Create a new layer (either clicking on the Create New Layer icon, which is located immediately to the left of the trash can on the Layers palette or by choosing *New Layer* ... from the Layers option menu or from the *Layers* menu, choose *New*, then choose *Layer*

Layers Channels Paths 💿
Normal Opacity: 100%
Lock: 🖸 🌶 💠 📓 🛛 Fill: 100% 🕨
Latent Print
Known Print
Create new layer button

- 9. Turn off the Latent Print layer by clicking the eye in the visibility panel of the Layers palette.
- 10. From the Swatches palette on the right side of your screen, choose a color that appears clearly visible for you.
- 11. From the *Toolbar*, select the *Line Tool*.
- 12. On the *Line Tool* options bar (directly below the Photoshop menu bar), choose the *Fill Pixels* option in the *Shapes* section. Then enable arrowheads by clicking on the *Geometry options*, and clicking in the box to the left of the *Start* option. Change *Width:* to 250% and *Length:* to 300%. Continuing moving to the right on the Line Tool options bar, set *Weight* to a value that equals 1% of the image resolution of the Chart image; *Mode* should remain at *Normal*; and *Opacity* should be reduced to 50%. The checkmark to the left of the box entitled Antialias, should be *off* (there should <u>not</u> be a checkmark in this box).

13. Using the line tool, position the cursor at the precise point used for alignment when the latent print was overlaid on top of the known print, and draw an arrow through another characteristic that is easily identifiable in both images.

14. Starting at the same beginning point, draw a second line through another characteristic that is located approximately 45 to 90 degrees away from the first line.

- 15. Turn on the latent print layer by clicking the blank space where the eye should appear in the visibility panel of the Layers palette, then click on the Latent Print layer in the Layers palette to make it the active layer.
- 16. Verify that the point in the latent print (used for overlaying the print) is positioned properly.

NOTE: While the point on the latent print should be positioned directly on top of the same point on the known print, the individual ridge characteristics will most likely not be in the same position due to the elasticity (stretching) of the skin. In many instances you must rotate the latent print so that the same characteristics can be aligned to touch along the corresponding lines.

17. Then verify that the lines drawn on the line layer dissect the same corresponding points on the latent print, just as they did on the known print.

18. Maximize the image window inside the Photoshop window. (You may need to fit the image to window - Ctrl + 0 - to make the entire image window fit on the Photoshop desktop as shown below.

- 19. If the latent print image must be rotated, from the *Edit* menu, choose *Free Trans*-*form* (or type Ctrl + T).
- 20. Move the pivot point of the Transform box so that it is positioned on top of the point used for aligning the images.
- 21. Move the cursor outside the Transform box (a two-headed cursor will appear when the cursor is outside the box). Click and hold down the left mouse button, and rotate the latent print until the corresponding characteristics of the latent print are aligned to the same angle (the corresponding characteristics should match up with the lines drawn for the known print). Hit Enter to complete the transform function and lock in the new latent print alignment.

22. In the Layers palette, click on Layer 1 to highlight the lines layer and drag the layer into the trash can at the bottom of the Layers palette.

Cropping, duplicating and separating the images

After the images have been properly calibrated and overlaid, and the rotation of the latent print matches that of the known print, it is time to crop the images so that only the corresponding portions of the prints will be used for the court chart. Additionally, using a duplicate copy of the overlaying images will help you verify the selection of corresponding characteristics. The original file containing the overlaid prints will be used to create the court chart, but the canvas size will have to be enlarged to make room to separate the two images as well as provide space for placement of the enlarged characteristics from both the latent and known prints.

1. Type the letter C to activate the crop tool. With the *Crop* tool, select the area of the prints that you want to use for your chart. (Remember, the latent print is overlaying the known print, and when you complete the crop, both images will be cropped to the same physical size and area.)

- 2. From the *File* menu, choose *Save as* ..., and then save this image as *Chart*. (In addition, I recommend that you use the Create New Folder option in the Save As dialog box (creating a folder that uses the case number as its name), and then save the Chart file in that folder.
- 3. From the *Image* menu, choose *Duplicate File*. When the duplicate image dialog box is displayed, type *Enlargements* in the name field and click OK.

4. From the *Image* menu, choose *Image Size*; then multiply the Resolution by 2.5. This will create enlargements of the selected characteristics that will be two and a half times larger than the life-size prints.

NOTE: Resample must be enabled – in other words, a checkmark must appear in the box immediately adjacent to Resample.

- 5. Type Ctrl + 0 (zero) to fit the *Enlargements* image to the Photoshop window.
- 6. Select the *Chart* window and change the *Canvas Size* (Alt + Ctrl + C). For optimum results, round the *Width* and *Height* values contained in this dialog box to the nearest tenth of an inch, <u>then</u>:

Canvas Size	×
Current Size: 2.81M Width: 0.55 inches Height: 0.618 inches	OK Cancel
New Size: 2.81M	
Width: 0.55 inches	
Height: 0.618 inches 💌	
C Relative	
Anchor:	
Canvas extension color; Background	

Canvas Size ... Before

- a. Multiply the rounded width value by 3 and then insert that value into the Width option of the Canvas Size dialog box.
- b. Multiply the rounded height value by 2 and then insert that value into the Height option of the Canvas Size dialog box.

Current Size: 2.81M Width: 0.55 inches	ОК
Height: 0.618 inches	Cancer
New Size: 17.9M	
Width: 1.8 inches	
Height: 1.2 inches	
C Relative	
Anchor:	
Canvas extension color: Background	

Canvas Size ... After

c. Click *OK* to accept the new Canvas Size.

- 7. Type Ctrl + 0 (zero) to fit the new canvas size to the Photoshop window.
- 8. In the *Layers* palette, select the Known Print Layer.
- 9. Type the letter *V* to activate the *Move* tool.
- 10. Use the *Move* tool together with the *Shift key* (constrained move) and move the known print to the right side of the canvas.
- 11. In the *Layers* palette, select the Latent Print Layer.
- 12. Use the *Move* tool together with the *Shift key* (constrained move) and move the latent print to the left side of the canvas.

NOTE: It is extremely important to verify that the top layer – Latent Print – is highlighted. You may need to click on that layer in the Layers Palette to verify that it is highlighted with the blue bar. All enlargements that you place on top of your image will go on top of the active (highlighted) layer.

Placing the enlargements on the chart

Now that the latent print and the known print have been separated on the canvas, it is time to copy the enlarged ridge characteristics and place them on the court chart.

NOTE: Before enabling the grid as defined in the following step, from the *Edit* menu, choose *Preferences*, then select *Guides*, *Grid & Slices*. In the portion of this dialog box entitled "Grid", change the color to a color value that you can easily see on your screen. Then change the *Gridline every:* setting to *9 inches* and the *Subdivisions:* to *99*.

- Chart @ 23% (Known Print, RGB/8)
- 1. From the *View* menu, select *Show* and then select *Grid*.

- 2. Select the *Enlargements* image by clicking on any visible part of the Enlargements image window.
- 3. From the *Toolbar*, choose the *Elliptical Marquee*.
- 4. On the *Elliptical Marquee* options bar, choose the *New Selection* option, then set *Feather* to a radius of *10 px* with *Anti-aliasing* enabled (a check mark should appear in the box to the left of *Anti-Alias*), and *Style* should be set to *Fixed Size*. Both *Width* and *Height* should be set to the same pixel dimensions.

Feather: 10 px 🔽 Anti-alias Style: Fixed Size 💽 Width: 255 px 🖨	Height: 255 px
📸 Enlargements @ 23.6% (Latent Print, RGB/8)	
A states	

NOTE: As a guideline, the Width and Height options should be set to somewhere between 10 and 20 percent of the image resolution of the <u>Chart</u> image, **NOT** the Enlargements image.

- 5. With the Latent Print layer active in Enlargements window, place the cursor over the characteristic to be used in the chart, then click the left mouse button to select that area. (If necessary, position the cursor inside the marching ants and click and hold the left mouse button and reposition the marching ants so that the latent print characteristic is centered inside the marching ants.)
- 6. Once the area has been selected, copy the selection by typing Ctrl + C.
- 7. Then click inside the Chart window to make it the active window.

NOTE: Be sure that the top layer, regardless of what layer it is, is always the active layer. The order of your layers will play a significant role when you draw lines or when you try to create your PowerPoint presentation.

- 8. Paste (Ctrl + V) the enlarged latent print characteristic from the Enlargements window onto the Chart window.
- 9. Select the Move tool (by typing the letter V or by selecting the Move tool from the Toolbar), and move the enlarged characteristic into position using the grid to guide you.
- 10. Click back on the Enlargements window.
- 11. On the Layers palette, turn off the visibility option for the Latent Print by clicking the eye icon to the left of the Latent Print layer.
- 12. Then click on the Known Print layer in the Layers palette to make it the active layer.
- 13. Select the Elliptical Marquee tool (by typing the letter M). (If necessary, position the cursor inside the marching ants and click and hold the left mouse button and reposition the marching ants so that the corresponding known characteristic is centered inside the marching ants.)
- 14. Copy the known print selection by typing Ctrl + C.
- 15. Click on the Chart window to make it the active window.
- 16. Always verify that the top layer in the Layers palette is highlighted, then paste (Ctrl + V) the enlarged known print characteristic into the Chart window.

NOTE: By verifying that the top layer is always the active layer, each time you paste a new enlargement, the layer number will increase by one, and the newest layer will be at the top of the layers palette as shown here.

If your layers are not in sequence – with the highest numbered layer at the top, you can re-order your layers by placing your cursor on the layer that you want to move, then click and hold the left mouse button and drag the layer to the appropriate location.

17. Select the Move tool (by typing the letter V or selecting the Move tool from the Toolbar), and move the enlarged known print characteristic into position using the grid to guide you.

- 18. Click back on the *Enlargements* window.
- 19. On the Layers palette, turn *on* the visibility option for the Latent Print by clicking the empty box where the eye icon should appear to the left of the Latent Print layer.
- 20. Then click on the Latent Print layer in the Layers palette to make it the active layer.
- 21. From the *Toolbar*, choose the *Elliptical Marquee* (Ctrl + M).
- 22. Repeat from step 5 to step 21 above for each pair of corresponding characteristics.

Drawing lines to identify the location of the ridge event

- 1. After you have finished copying all of the characteristics onto the Chart window, choose the Rectangular Marquee.
- 2. On the *Rectangular Marquee* options bar, choose the *New Selection* option, then verify that *Feather* is set to a radius of *0 px* (feathering must be disabled for this task), and *Style* should be set to *Normal*.

		Feather:	px 🔽 Anti-alia	as Style: N	ormal	• W	ïdth:	4	Height:	
×	🔞 Chart.tif @	3 2.1% (La	yer 12, RGB/8)							

- 3. Using the grid as your guide, position the cursor just above and to the left of the latent print enlargements, then click and hold the left mouse button and create a box (marching ants) around the latent print.
- 4. Then press and hold the shift key and again using the grid as your guide, position the cursor just above and to the right of the known print enlargements, then click and hold the left mouse button and create a box (marching ants) around the known print. You will now have two sets of marching ants.

- 5. Once again, please verify that the top layer in the Layers palette is active (this layer is highlighted with the blue bar).
- 6. Click on the Create Layer option at the bottom of the Layers palette.

NOTE: Using the Create Layer option, you can also create an additional layer for each pair of lines to correspond with each matching pair of characteristics. Then, using the visibility option for both the enlarged characteristics and line pair, you can control the display of characteristics and lines.

- 7. From the *Toolbar*, select the *Line Tool*.
- 8. On the *Line Tool* options bar (directly below the menu bar), choose the *Fill Pixels* option in the *Shapes* section. Then enable arrowheads by clicking on the *Geometry options*, and clicking in the box to the left of the *Start* option, and change *Width:* to 250% and *Length:* to 300%. Continuing moving to the right on the Line Tool options bar, set *Weight* to a value that equals 1% of the image resolution of the Chart image; *Mode* should remain at *Normal*; and *Opacity* should be reduced to 50%. The checkmark to the left of the box entitled Antialias, should be *off* (there should <u>not</u> be a checkmark in this box).

9. Position the cursor on the latent print at the location of the ridge event shown in the first pair of characteristics. Then click and hold the left mouse button and drag the cursor to the center of the left edge of the enlarged latent characteristic and release the left mouse button.

When you release the mouse button, a line will appear with the arrowhead pointing at the first ridge event, terminating at the marching ants - the edge of the marquee box.

10. Position the cursor on the known print at the location of the ridge event shown in the first pair of characteristics. Then click and hold the left mouse button and drag the cursor to the center of the right edge of the enlarged known print characteristic and release the left mouse button.

When you release the mouse button, a line will appear with the arrowhead pointing at the first ridge event, terminating at the marching ants - the edge of the marquee box.

11. As stated in step 6, you can create a new layer for pair of lines.

12. Repeat steps 9 through 11 for each matching pair of ridge characteristics.

Using the Type tool to label the chart

- 1. After all line pairs are drawn, turn off the marquee (the marching ants) by deselecting (Ctrl + D) the selected areas.
- 2. From the tool bar, choose the Type tool.
- 3. In the Type Tool options bar, change the font type to *Arial* and *Regular* for style. In the type size list box, select *8 pt* (as the image is still set for 1:1 life size); *aa* (anti-aliasing) should be set to smooth. Choose any of the desired alignment boxes as well as the desired color for the text on your chart.
- 4. Click in the Chart window above the latent print image and type the words *Latent Print*.

NOTE: When the pointer (mouse) cursor is moved away from the text, the Move tool icon will appear. Click and hold the left mouse button to fine tune the position of the text.

- 5. Once you are satisfied with the position of the text, commit your text by either clicking the *Commit Any Current Edits* button on the left side of the Type Options bar or by pressing the enter key to the right of the numeric keypad on your keyboard or by clicking on the Type layer on the Layers palette.
- 6. Click in the Chart window above the known print image and type the words *Known Print*.

NOTE: When the pointer (mouse) cursor is moved away from the text, the Move tool icon will appear. Click and hold the left mouse button to fine tune the position of the text.

- 7. Once you are satisfied with the position of the text, commit your text by either clicking the *Commit Any Current Edits* button on the left side of the Type Options bar or by pressing the enter key to the right of the numeric keypad on your keyboard or by clicking on the Type layer on the Layers palette.
- 8. From the *View* menu, choose *Show*, and then choose *Grid* to turn off the grid.

- 9. From the *Image* menu, choose *Image Size*. When the *Image Size* dialog box appears, ensure that Resample is turned off (a check mark should not appear in the box to the left of the Resample option at the bottom of the Image Size dialog box).
- 10. In the Resolution field, type 300 (or the appropriate resolution for your output printer device).

Description	

12. Save your final chart.

Creating a PowerPoint Presentation

When saving your final chart, you must save your chart either as a TIF (Tagged Image File) or PSD (PhotoShop Document) file format. Both of these file formats provide the ability to save multiple layers within a single file. As I am sure you have now realized, your chart contains numerous layers. The last thing you want to do is lose the ability to separate and display the individual layers as needed. For example, your layers palette might look something like this:

	Ξ×
Layers Channels Paths	۲
Normal Opacity: 100%	_
Lock: 🖸 🖉 🕂 🚔 Fill: 100% 🕨	
T LATENT PRINT

Layer 11	
Lines 5	
Layer 10	
Layer 9	_
Lines 4	
Layer 8	
Layer 7	
Lines 3	
Layer 6	
Layer 5	
Lines 2	
Layer 4	
Layer 3	
Lines 1	
Layer 2	
Layer 1	
Latent Print	
S Known Print	•
60 Ø. D Ø. L 1 5	9 📈

Hopefully, you used the create layer button at the bottom of the Layers palette to create a blank layer after each pair of corresponding ridge events were pasted onto the Chart window. (As shown above, I labeled the layer for each pair of lines to correspond with the set number for ease of reference. For example, for the characteristics on Layer 1 and Layer 2, the line pair was identified as Lines 1; for Layer 3 and 4, the line pair was identified as Lines 2; so on and so forth.)

Following this procedure, you can turn on or off the visibility option for not only each characteristic, but for each pair of lines as well.

By turning on the layer visibility option, you can control which layers are viewed as well as which images are saved when you save your images in specific formats, such as JPG.

NOTE: Microsoft PowerPoint uses a standard display resolution of 72 PPI. You can insert files with a higher resolution, however, they display much slower than those with the lower resolution, your PowerPoint files will be much larger, and some high resolution TIF files can be too large to be included as a PowerPoint slide.

Therefore, I recommend that you use the maximum JPG image quality setting (shown below) when you save your image files in Adobe Photoshop. This procedure creates individual image files that are both flattened and will display only the visible layers as well as provides sufficient image quality – yet small enough image files – for use in PowerPoint.

Matte: None Image Options Quality: Maximum amail file Image file Format Options Format Options Format Options Format Optimized Progressive Scans: Size V280.87K / 367.54s S56.6Kbps	Cancel

Saving your files

After you have completed your chart, you must save your files in a format that is compatible (both in terms of file size and image quality) with Microsoft PowerPoint. The following steps define the procedure for creating a series of files that will help facilitate and move your discussion through the identification process from analysis, comparison and evaluation of the fingerprint pattern (Level 1 detail) through the discussion of the ridge events (both Level 2 and 3 detail as well as location of the ridge events).

- 1. Create your chart. (Be sure to include a separate layer after each pair of corresponding ridge events so that you separate the lines for each corresponding pair of ridge events.)
- 2. Turn off the visibility for all ridge event layers and all line layers. Leave on the latent print and known print layers as well as any background layers (such as the stroke layer for the border, logos, type layers, etc.).
- 3. Save your Chart image in either a TIF or PSD format to preserve your final, non-compressed file.

NOTE: When saving your image, we recommend that you create a separate folder to hold your chart files as you will be creating a series of files in this process. It will also make the process of inserting the images into PowerPoint much easier.

- 4. From the File menu, choose Save As ... to save your Chart image with all layers turned off except those layers identified in step 2 above as a JPG file using a file name such as CHART.JPG. This first slide will be used to discuss the correspondence of Level 1 detail.
- 5. When the *JPEG Options* dialog box is displayed, ensure that *Quality* is set to *12 Maximum* under Image Options as shown above, then click OK.

6. Turn on the layers (click in the blank visibility option boxes) for the first pair of characteristics. This will allow you to include a slide in your presentation that illustrates just the correspondence between the characteristics (Level 2 and Level 3 detail) as well as maintain the focus on the similarity of characteristics without the distraction of identifying the physical location of the characteristics.

- 7. From the File menu, choose Save As ... to save your Chart image with just the first two layers turned on as a JPG file using a filename such as CHART1.JPG. When the *JPEG Options* dialog box is displayed, verify that *Quality* is set to 12 *Maximum* under Image Options, then click OK.
- 8. Turn on the layer (click in the blank visibility option box) for the first pair of lines. Once you have described the consistency between the Level 2 detail, you can then describe the physical location of the characteristics within the two images. As additional characteristics and their line sets are displayed, you can

discuss other similarities, such as ridge counts, etc., without the distraction of explaining the different types of ridge events (Level 2 and Level 3 detail).

- 9. From the File menu, choose Save As ... to save your Chart image with just the first two layers turned on as a JPG file using a filename such as CHART1L.JPG. When the *JPEG Options* dialog box is displayed, verify that *Quality* is set to 12 *Maximum* under Image Options, and then click OK.
- 10. Repeat steps 6 through 9 above for each pair of ridge events as well as the corresponding pair of lines. (You can use a simple one-up numbering system when you save each pair of JPG files, where the next number indicates the next pair of ridge events, and the corresponding letter L indicates the set of lines for that pair.)

Inserting the files into PowerPoint

After you have saved all of the files for your matching ridge events and corresponding line pairs, you are ready to begin constructing your PowerPoint presentation.

- 1. Start up Microsoft PowerPoint.
- 2. From the File menu, choose New. A new blank presentation will be opened and the New Presentation palette (as shown below) will be displayed on the right side of your screen.

- 6. Navigate to the directory where you stored the JPG files for your chart, then select the first image file (such as CHART.JPG) from the Insert File dialog box. (If you saved your original chart file as described in the procedures for creating a chart, your image size will be formatted to fit perfectly in the blank slide.)
- 7. From the *Insert* menu, choose *New Slide* (*Ctrl* + *M*).
- 8. From the *Contents Layout* portion of the *Slide Contents* palette, choose the *Blank* slide layout.
- 9. From the *Insert* menu, choose *Picture*, and then choose *From File* Then select the next image (in order) for this slide.
- 10. Repeat steps 7 through 9 above for each file that you want to include in your presentation. Your final presentation will consist of several slides:

11. After you have inserted all files, be sure to save your PowerPoint presentation! For ease of reference as well as ease of finding all related files, I recommend that you save your final presentation file in the same folder that contains your original chart file (CHART.TIF) as well as your separate JPG files.

Good luck with your presentation! I am confident you will definitely make your point in court. And speaking of points, using this type of presentation, you won't have to worry about the age old question of counting points, because you can clearly demonstrate that it's not about points, but it is about the agreement and consistency of Level 1, 2 and 3 details.
